

The largest mean margin does not align the most pairs

600 matched human-voted pairs · every dot is one pair · counts above report $m > 0$

$m = \text{mean log p}(\text{human-preferred}) - \text{mean log p}(\text{rejected})$; zero is the alignment boundary

Violin density is computed after a monotone asinh transform (scale 0.25); all signs, pair counts, and outliers are retained.
